Experiment 10

Dockerfile is a text file that contains a set of instructions used to automatically build a Docker image. It defines the base image, environment, dependencies, and commands required to run an application inside a container.

1. Dockerfile Overview

A Dockerfile consists of step-by-step instructions that Docker follows to create an image. Each instruction in the Dockerfile creates a new layer in the image.

Common Dockerfile instructions include:

- **FROM**: Specifies the base image
- **RUN**: Executes commands during image build
- **COPY / ADD**: Copies files into the container
- **WORKDIR**: Sets working directory
- **CMD / ENTRYPOINT**: Defines default command to run

2. Pulling an Image from Docker Hub

The command:

docker pull hello-world

is used to download an image from Docker Hub.

Explanation:

- Downloads the hello-world image from the official Docker repository
- If not present locally, Docker fetches it from the remote registry
- The image is stored locally for future use
- Output shows layers being downloaded and image digest

3. Listing Available Docker Images

The command:

docker images displays all locally available

Docker images.

Explanation:

- Shows repository name, tag, image ID, size, and creation details
- Confirms successful image download
- Helps manage and identify images stored in the system

4. Building a Docker Image

A Docker image is built using the

command: docker build -t <image_name> .

Explanation:

- Builds an image from the Dockerfile in the current directory
- -t is used to assign a name (tag) to the image
- Docker processes each instruction in the Dockerfile step-by-step
- Final output is a reusable image

5. Running a Docker Container

The command:

docker run hello-world is used to run a

container from the specified image.

Explanation:

- Docker checks if the image is available locally

- If not, it pulls the image from Docker Hub
- Creates a new container from the image
- Executes the default command defined in the image
- Displays output in the terminal

6. Working of Hello-World Container

When the hello-world container is executed, the following steps occur:

- Docker client sends request to Docker daemon
- Docker daemon pulls the image (if not available locally)
- A container is created from the image
- The container runs a simple program that prints a message
- Output is sent back to the terminal

This confirms that Docker is installed and functioning correctly.

7. Image Storage and Layers

Docker images are built using a layered architecture:

- Each instruction in a Dockerfile creates a layer
- Layers are cached to improve performance
- Images are stored in the local Docker registry

Conclusion

Thus, Dockerfile provides a structured way to define application environments and build Docker images. Commands like docker pull, docker images, docker build, and docker run help in managing images and running containers. The successful execution of the hello-world container confirms proper Docker setup and understanding of image execution workflow.

```
C:\Users\15L>docker pull hello-world
Using default tag: latest
latest: Pulling from library/hello-world
17eec7bbc9d7: Pull complete
Digest: sha256:ef54e839ef541993b4e87f25e752f7cf4238fa55f017957c2eb44077083d7a6a
Status: Downloaded newer image for hello-world:latest
docker.io/library/hello-world:latest

C:\Users\15L>
```

```
C:\Users\15L>docker run hello-world

Hello from Docker!
This message shows that your installation appears to be working correctly.

To generate this message, Docker took the following steps:
 1. The Docker client contacted the Docker daemon.
 2. The Docker daemon pulled the "hello-world" image from the Docker Hub.
    (amd64)
 3. The Docker daemon created a new container from that image which runs the
    executable that produces the output you are currently reading.
 4. The Docker daemon streamed that output to the Docker client, which sent it
    to your terminal.

To try something more ambitious, you can run an Ubuntu container with:
 $ docker run -it ubuntu bash
